Hierarchical MnMoO₄/CoMoO₄ heterostructured nanowires with enhanced supercapacitor performance

Li-Qiang Mai^{1,2}, Fan Yang¹, Yun-Long Zhao¹, Xu Xu¹, Lin Xu^{1,2} & Yan-Zhu Luo¹

Recent attention has been focused on the synthesis and application of complex heterostructured nanomaterials, which can have superior electrochemical performance than single-structured materials. Here we synthesize the three-dimensional (3D) multicomponent oxide, MnMoO₄/CoMoO₄. Hierarchical heterostructures are successfully prepared on the backbone material MnMoO₄ by a simple refluxing method under mild conditions; and surface modification is achieved. We fabricate asymmetric supercapacitors based on hierarchical MnMoO₄/CoMoO₄ heterostructured nanowires, which show a specific capacitance of 187.1 F g⁻¹ at a current density of 1 A g⁻¹, and good reversibility with a cycling efficiency of 98% after 1,000 cycles. These results further demonstrate that constructing 3D hierarchical heterostructures can improve electrochemical properties. 'Oriented attachment' and 'self-assembly' crystal growth mechanisms are proposed to explain the formation of the heterostructures.

As energy storage devices with properties intermediate to those of batteries and electrostatic capacitors, electrochemical supercapacitors exhibit the desirable properties of high power density (ten times more than batteries), fast charging (with seconds), excellent cycling stability, small size and low mass, which make them one of the most promising candidates for next-generation power devices^{1–7}. With characteristics complementary to those of rechargeable batteries and fuel cells, supercapacitors have been used in many applications, such as power back-up, pacemakers, air bags and electrical vehicles⁸. Currently, most commercial supercapacitors are made of high-surface-area carbonaceous materials². However, these supercapacitors might not provide sufficient energy/power densities or efficiencies, and the specific capacitance severely decreases under high current. Therefore, much attention has been focused on improving the capacitance of supercapacitors, and their performance at high current densities, by constructing complex heterostructures with increased surface areas.

Three-dimensional (3D) hierarchical heterostructures with high surface/body ratios, large surface areas, better permeabilities and more surface active sites have potential in optical, catalytic and electrochemical applications^{9–15}. Thus, the synthesis and application of 3D hierarchical heterostructures will be a focus of the nanomaterial research field^{16–19}. Mai *et al.* have synthesized ultra-long hierarchical vanadium oxide nanowires by electrospinning, which exhibit much higher capacity in lithium ion batteries²⁰. Meng *et al.* synthesized 3D Bi₂WO₆/TiO₂ to enhance photocatalytic activity and found that the heterostructures exhibited much higher photodegradation efficiency than Bi₂WO₆ and TiO₂ (ref. 19).

The molybdates MnMoO₄ and CoMoO₄ have excellent catalytic and electrochemical characteristics^{21–23}. In this paper, hierarchical MnMoO₄/CoMoO₄ heterostructured nanowires were controllably synthesized using a facile refluxing method under mild conditions. MnMoO₄ nanowires form the backbone material, and the CoMoO₄ shell thickness could be tuned by changing the molar ratio of Mn source and Co source. The superior electrochemical performance of the structure was demonstrated.

Results

Characterization of MnMoO₄/CoMoO₄ heterostructured nanowires. To determine the phase structures of the products, the X-ray diffraction (XRD) measurements were conducted. The backbone material MnMoO₄ nanowires (MnMoO₄; JCPDS card No. 01-072-0285; MnMoO₄·0.9H₂O; JCPDS card No. 00-050-1286) were identified by the XRD pattern shown in Figure 1a (black line). The hierarchical MnMoO₄/CoMoO₄ heterostructured nanowires (open circles, open squares; JCPDS card No.00-021-0868) were identified in Figure 1a (red line). Because MnMoO₄ (No.01-084-2102: *a* = 10.469 Å, *b* = 9.516 Å, *c* = 7.143 Å) has a similar crystal lattice parameter as CoMoO₄ (No.00-021-0868: *a* = 10.210 Å, *b* = 9.268 Å, *c* = 7.022 Å), lattice matching between MnMoO₄ and CoMoO₄ can exist. Raman

spectroscopy was applied to further investigate the structural change in bonding related to the hierarchical heterostructure (Fig. 1b). For those structures, the strong bands observed between 200 and 1,200 cm⁻¹ can be assigned to bend and stretching frequencies of those materials. The band at 872 cm⁻¹ in hierarchical MnMoO₄/CoMoO₄ heterostructured nanowires was not found in pure CoMoO₄ nanorods or backbone MnMoO₄ nanowires, which may be assigned to the new stretching vibration of Co–O–Mn.

Figure 2a–d shows the scanning electron microscopy (SEM) images of the MnMoO₄ nanowires and obtained MnMoO₄/CoMoO₄ heterostructured nanowires. In Figure 2a, pure MnMoO₄ nanowires with the length of 10 μm and the diameter of 500 nm were used as the backbone material. The hierarchical heterostructures of the MnMoO₄/CoMoO₄ sample are shown in Figure 2b–e. With the extension of reaction time, CoMoO₄ nanorods with higher density grew aslant on the primary MnMoO₄ nanowires (Supplementary Fig. S1). Further information about MnMoO₄/CoMoO₄ hierarchical heterostructure was obtained from transmission electron microscopy (TEM) (Fig. 2d). It is confirmed that CoMoO₄ nanorods have diameters of about 50 nm. Close inspection at the heterojunction shows that the CoMoO₄ nanorods have their roots inside the MnMoO₄ nanowires, suggesting that the CoMoO₄ nanorods are not just loosely attached to the nanowire surface. The high-resolution TEM investigation (Fig. 2e) demonstrates that the interlayer distances are consistent with the interplanar distances of CoMoO₄ (0.335 nm) and MnMoO₄ (0.288 nm). These results suggest that the prepared sample is considered to be a well-crystallized heterostructure with MnMoO₄/CoMoO₄ on nanoscale. Energy dispersive spectroscopy (EDS) microanalysis on selected areas was shown in Figure 2f. The ‘shell’ of the heterostructures consists of Co, Mo and O (the inset of Fig. 2f) elements, whereas the entire heterostructures consist of Mn, Co, Mo and O (Fig. 2f), indicating that the nanorods grown on the surface are mainly made of CoMoO₄ and the parent hierarchical heterostructures are a mixture of MnMoO₄ and CoMoO₄, which agrees well with the results of XRD analysis. A MnMoO₄/CoMoO₄ nanocomposite without 3D hierarchical heterostructures was also synthesized by a simple refluxing method, as a control experiment (Supplementary Fig. S2).

Crystal growth mechanism. The crystal growth mechanism of ‘self-assembly’ and ‘oriented attachment’ were proposed to demonstrate the complicated nano-architecture process. The oriented attachment mechanism describes the spontaneous self-organization of adjacent particles, so that they share a common crystallographic orientation, followed by the joining of these particles at a planar interface. The process is particularly relevant in the nanocrystalline regime, where bonding between the particles reduces overall energy by removing surface energy associated with unsatisfied bonds²⁴. In the reaction, MnMoO₄ nanowires were used as the ‘substrate’, which can guide the CoMoO₄ self-assembling growth in aqueous solution without surfactant and stabilizers. Then the ‘oriented attachment’ can guide the nanoparticles oriented growth. As shown in Figure 3, supersaturated solution with plenty of CoMoO₄ small crystals were formed by adding Co resource. Because of the high surface energy and thermodynamics instability, nanoparticles can attach to the surface of MnMoO₄ to decrease surface energy. The crystallographic orientation of the particles with respect to each other is determined by the minimization of the highest surface energy. Therefore, with a matching lattice, the lattice fringes’ orientation and crystal growth direction are uniform to some extent. The ‘substrate’, MnMoO₄, has similar lattice parameters and can control CoMoO₄ nanoparticle self-assembly and oriented crystallization to form hierarchical MnMoO₄/CoMoO₄ heterostructured nanowires.

Electrochemical properties. Figure 4a,b displays the galvanostatic charge–discharge curves of hierarchical MnMoO₄/CoMoO₄

(d, e) TEM and high-resolution TEM images at the heterojunction of hierarchical $\text{MnMoO}_4/\text{CoMoO}_4$ heterostructured nanowires. (f) The EDS microanalysis on selected areas. Scale bars, $1\ \mu\text{m}$ (a–c); $20\ \text{nm}$ (d); $5\ \text{nm}$ (e).

Figure 3 | The construction of hierarchical $\text{MnMoO}_4/\text{CoMoO}_4$ nanowires. The green rod represents the backbone MnMoO_4 nanowire, and orange rods the CoMoO_4 nanorods. Red and blue balls are different ions dispersed in the aqueous solution.

heterostructured nanowires and $\text{MnMoO}_4/\text{CoMoO}_4$ nanocomposite (No 3D), MnMoO_4 nanowires, CoMoO_4 in 2 M NaOH at room temperature. The specific capacitance has been calculated from equation (1):

$$C(F/g) = \frac{i\Delta t}{m\Delta V} \quad (1)$$

Where i (A) is the current density used for charge/discharge, Δt (s) is the time elapsed for the discharge cycle, m (g) is the weight of the active electrode and ΔV (V) is the voltage interval of the discharge. The specific capacitance and energy density calculated from each discharge curve are shown in Figure 4c. The hierarchical $\text{MnMoO}_4/\text{CoMoO}_4$ electrodes can reach to 204.1, 187.1, 163.4, 134.7 F g^{-1} and 28.4, 26.0, 22.7, 18.7 Wh kg^{-1} at 0.5, 1, 2, 3 A g^{-1} . The capacitance for hierarchical $\text{MnMoO}_4/\text{CoMoO}_4$ heterostructured nanowires is significantly higher than that for pure one-dimensional nanorods (MnMoO_4 : 9.7 F g^{-1} , 8.8 Wh kg^{-1} ; CoMoO_4 : 62.8 F g^{-1} , 1.4 Wh kg^{-1} ; $\text{MnMoO}_4/\text{CoMoO}_4$ nanocomposite: 69.2 F g^{-1} , 9.6 Wh kg^{-1} at a charge–discharge current density of 1 A g^{-1}). The hierarchical $\text{MnMoO}_4/\text{CoMoO}_4$ heterostructured nanowire electrode exhibited good reversibility with cycling efficiency of 98% after 1,000 cycles shown in Figure 4d.

As reported, at low current densities, due to the low ohmic drop, the inner active sites or the pores of the electrode can be fully accessed; hence, high specific capacitance values can be achieved²⁵. However, high current densities are of great importance in industrial applications. The measuring conditions of hierarchical $\text{MnMoO}_4/\text{CoMoO}_4$ heterostructured nanowires were implemented at higher current

densities. The result reveals that the observed specific capacitance values 204.1 F g^{-1} for the hierarchical $\text{MnMoO}_4/\text{CoMoO}_4$ electrodes are higher than those reported, such as MoO_2 (ref. 3), MnO_2 (ref. 26) and Co_3O_4 (ref. 27), at similar current densities to a certain extent.

Discussion

To explain the electrochemical results, it is important to consider the hierarchical $\text{MnMoO}_4/\text{CoMoO}_4$ heterostructured nanowires that exert such a significant influence on charge storage. This consideration is closely related to the Brunauer–Emmet–Teller (BET) surface area (Supplementary Fig. S3). The BET surface area of MnMoO_4 is 3.17 m^2g^{-1} , $\text{MnMoO}_4/\text{CoMoO}_4$ nanocomposite is 28.0 m^2g^{-1} and $\text{MnMoO}_4/\text{CoMoO}_4$ (3D) after surface modification can reach to 54.06 m^2g^{-1} , which is larger than that reported in the literature (MnMoO_4 nanorods 15 m^2g^{-1} and CoMoO_4 nanorods 25 m^2g^{-1} with smaller size²⁸), so the inner active sites of the electrode can be fully accessed with large surface area. Besides, compared with self-aggregated short CoMoO_4 and MnMoO_4 nanorods synthesized by hydrothermal and micro-emulsion method, the hierarchical $\text{MnMoO}_4/\text{CoMoO}_4$ heterostructured nanowires exhibit much higher capacity. This is due to the fact that self-aggregation of the hierarchical $\text{MnMoO}_4/\text{CoMoO}_4$ heterostructured nanowires have been greatly reduced, which can keep the effective contact areas of active materials and electrolyte large and sufficient. Third, in comparison with pure CoMoO_4 nanorods, the highly dense small CoMoO_4 nanorods grow on the MnMoO_4 ‘substrate’ orderly but with low crystallinity. This structure can provide surface sites for redox reaction, and possess sufficient order to enable OH^- access to the heterostructures facilely. It would seem, therefore, that the facile ability of OH^- to be inserted is an extra account for the enhanced charge storage of hierarchical $\text{MnMoO}_4/\text{CoMoO}_4$ heterostructured nanowires. These factors are expected to contribute to the substantial level of capacitive ability for supercapacitors.

The cyclic voltammogram (CV) is performed to identify the charge storage mechanism in $\text{MnMoO}_4/\text{CoMoO}_4$. Figure 4e shows the CVs of $\text{MnMoO}_4/\text{CoMoO}_4$. Comparing to the MnMoO_4 and CoMoO_4 electrodes (Supplementary Fig. S4), one more pair of redox peaks can be observed in the CV curves of $\text{MnMoO}_4/\text{CoMoO}_4$, which indicate that the pseudocapacitance mainly comes from the Faradic redox reaction of both Mn and Co. Comparing to the Pourbaix diagram of Mn, Co and Mo (Supplementary Fig. S5)²⁹, Faradic redox reactions are as follows:

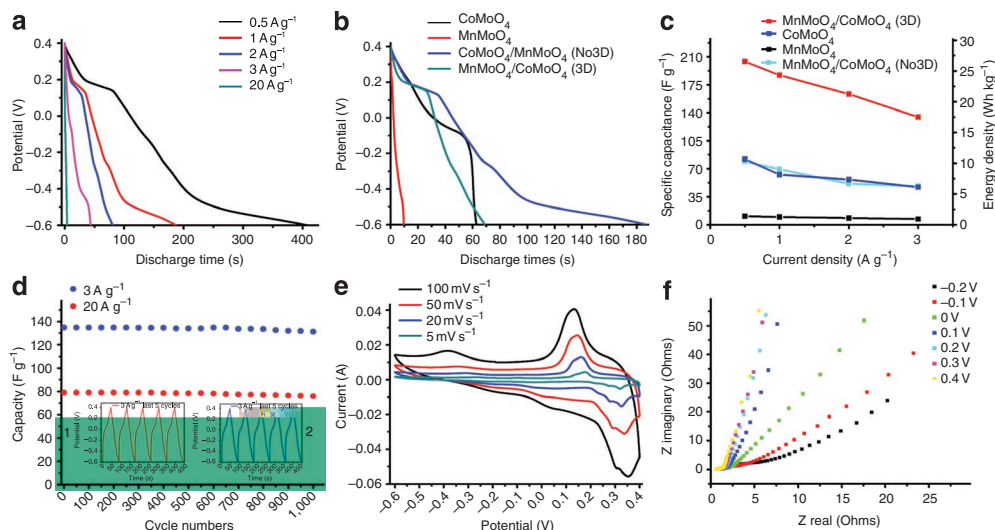

Figure 4 | Electrochemical characterizations in 2M NaOH aqueous solution at room temperature. (a) Galvanostatic charge-discharge curves of hierarchical MnMoO₄/CoMoO₄ heterostructured nanowire electrodes at different current density. (b) Galvanostatic charge-discharge curves of MnMoO₄, CoMoO₄, MnMoO₄/CoMoO₄ nanocomposite (No 3D), MnMoO₄/CoMoO₄ (3D) electrodes at current density of 1 A g⁻¹. (c) Specific capacitance and energy density of different electrodes at different current density. (d) Charge-discharge cycling test of MnMoO₄/CoMoO₄ (3D) electrodes at the current density of 3 and 20 A g⁻¹, showing 2% loss after 1,000 cycles; inset shows the galvanostatic charge-discharge cyclic curves of the first and last five cycles at 3 A g⁻¹. (e) Cyclic voltammogram curves of MnMoO₄/CoMoO₄ (3D) electrodes. (f) AC impedance plots of MnMoO₄/CoMoO₄ electrodes.

Supplementary Figure S4 and Figure 4e show that with the increase of the scan rate, the redox current increased, the anodic peak shifted towards positive potential and the cathodic peak shifted towards negative potential. The peak current increases nearly linearly with the scan rate confirming the pseudocapacitive behaviour. The increase of the current response with the scan rate also indicates that the kinetics of interfacial Faradic redox reactions and the rates of electronic and ionic transport are even rapid enough at scan rates as high as 100 mV s⁻¹.

Figure 4f displays the Nyquist plots of MnMoO₄/CoMoO₄ at different voltage. The semicircle in the high-frequency range corresponds to the charge-transfer resistance caused by the Faradic reaction, which was correlated with the intercalation and deintercalation of cations. Between 0.1–0.4 V, the plots in the low-frequency range correspond to the diffusion-limited mechanism, which confirms that the main pseudocapacitive behaviour occurred between 0.1–0.4 V. The result is concordant with the two pairs of redox peaks of CVs.

In summary, a mild facile refluxing method was used to fabricate hierarchical MnMoO₄/CoMoO₄ heterostructured nanowires possessing a specific capacitance of 187.1 F g⁻¹ at a high current density of 1 A g⁻¹ and a good reversibility with cycling efficiency of 98% after 1,000 cycles. This demonstrates that constructing hierarchical MnMoO₄/CoMoO₄ nanowire heterostructures by combining ‘oriented attachment’ and ‘self-assembly’ is a significant and simple route to improve electrochemical properties. The hierarchical MnMoO₄/CoMoO₄ nanowire heterostructure described in this paper may have potential applications in energy storage and other electrochemical devices.

Methods

Synthesis of MnMoO₄/CoMoO₄ heterostructured nanowires. MnMoO₄ nanowires, the backbone material, were prepared by simple micro-emulsion method with Na₂MoO₄ and MnCl₂. The synthesis of hierarchical MnMoO₄/CoMoO₄ heterostructured nanowires was performed in a flask with mild magnetic

stirring for different periods. Typically, MnMoO₄ nanowires were dispersed in 40 ml water and the dispersion was refluxed at 60 °C. Then, CoCl₂ and the same amount of Na₂MoO₄ were added to the mother solution discontinuously. To follow the crystal growth process, the samples were taken at different time intervals. Then the sample was washed with deionized water and ethanol, and dried for further characterization. The CoMoO₄ shell thickness could be tuned by changing the molar ratio of Mn source and Co source.

Characterization and electrochemical measurement. The crystal phase and purity of the product were characterized by X-ray powder diffraction. XRD patterns of the products were recorded on a Rigaku D/MAX-III diffractometer (Rigaku) with monochromatized Cu Kα radiation ($k = 1.5406 \text{ \AA}$). SEM performed on JSM-5610LV was used to characterize the morphology of the synthesized nanomaterials. TEM, high-resolution TEM were recorded by using a JEOL JEM-2010 FEF microscope (JEOL) at an accelerating voltage of 200 kV. EDS was performed on a JEM 2100F STEM/EDS and the X-ray energy resolution is 132 eV. Laser Raman spectrometer was recorded using the INVIA, Renishaw. BET surface areas were measured using Gemini 2360 instrument by adsorption of nitrogen at -209 °C. A three electrodes method consisting of a nickel foam as working electrode (0.07 cm²), Pt wire and Ag/AgCl (saturated KCl) electrodes as counter and reference electrodes were used. Cyclic voltammetry and galvanostatic charge-discharge studies were performed using an Autolab Potentiostat Galvanostat. NaOH (2.0 M) was used as the electrolyte. The working electrode consisted of 60 wt% of the active material (for example, MnMoO₄/CoMoO₄), 35.5 wt% of conductivity agent (carbon black, Super-P-Li) and 4.5 wt% of binder (polytetrafluoroethylene).
